A B D C D C D ...  
B B B D G H A ...  
B B D D D E H ...  
...

state machine learning

software model

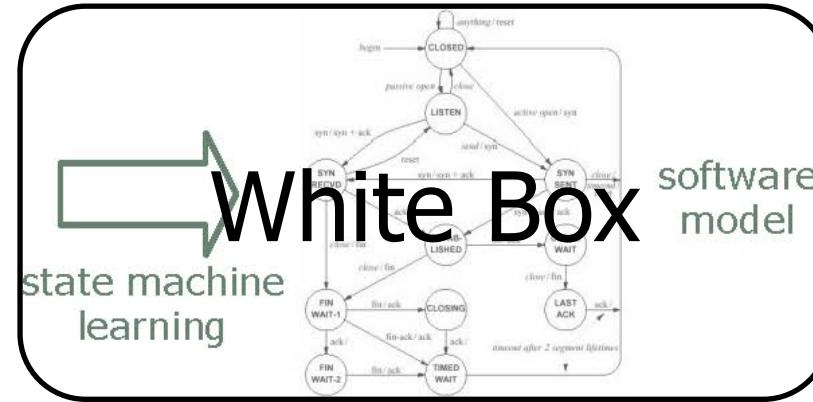

- Software leaves **traces**
- A state machine is a **logical model** describing these traces
  - Classification – is a new trace generated by the same software?
  - Prediction – what trace is most likely to occur next?
  - **Analysis** – is the software deadlock-free, secure, **malicious?**

# System identification and analysis

Black Box

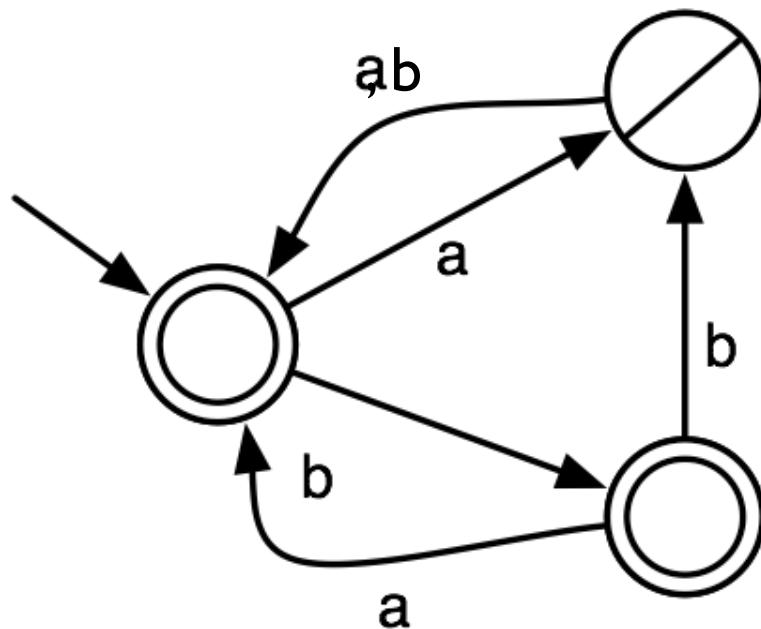

execution traces

A B E E E E D ...  
A B D C D C D ...

# Deterministic finite state automata (DFA)

$(a,-), (ab,+), (aa,+), (b,+), (bb,-), (bab,+)$

# State machine learning

- Input:
  - Data, e.g., (a,+) (b,-) (aba,+) (abaa,-) (bbb,+) (bba,+)
- Goal: Find a smallest DFA that is **consistent** with the data
- Size is measured by the number of states/transitions
  - Occam's razor:

*Among competing hypotheses, the one with the fewest assumptions should be selected.*

- Consistency is:
  - Accepts all positive, rejects all negative

# Example

accept:

1 0 0 0 0 0 0 0  
0 1 1 0 0 0 1 0 1 0 1 0 1 0 0  
0 0  
1 0 1 0 0  
1 0 0  
1 0 1  
1 0 1  
1 0 0 0 0 0 0

reject:

0 1 0 0 0  
1 1 0 0 0 0 0 0 1 0 0  
0 0 0 0 0 1  
1 0 0 0 0 1 0 1 0 0 0 0 1 1 1 0 0 0  
0 1 1 1 0 1 0 0 0 0 0 0

What is the smallest state machine that accepts the top and rejects the bottom strings?

**Guess: how many states are needed?**

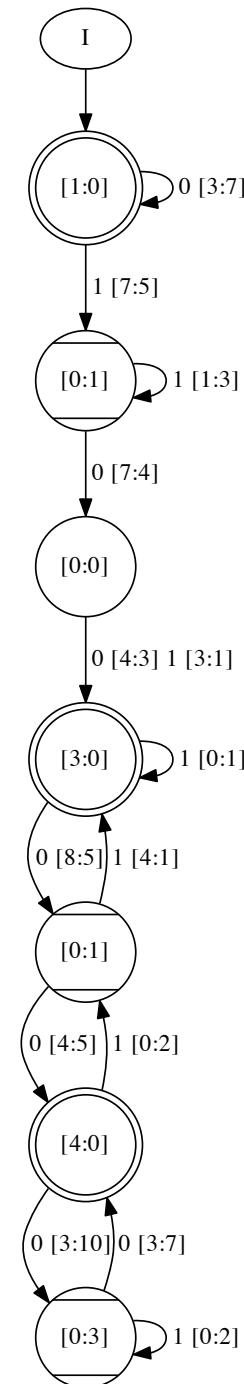

# Example

accept:

```
1 0 0 0 0 0 0 0  
0 1 1 0 0 0 1 0 1 0 1 0 1 0 0  
0 0  
1 0 1 0 0  
1 0 0  
1 0 1  
1 0 1  
1 0 0 0 0 0 0
```

reject:

```
0 1 0 0 0  
1 1 0 0 0 0 0 0 1 0 0  
0 0 0 0 0 1  
1 0 0 0 0 1 0 1 0 0 0 0 1 1 1 0 0 0  
0 1 1 1 0 1 0 0 0 0 0 0 0
```

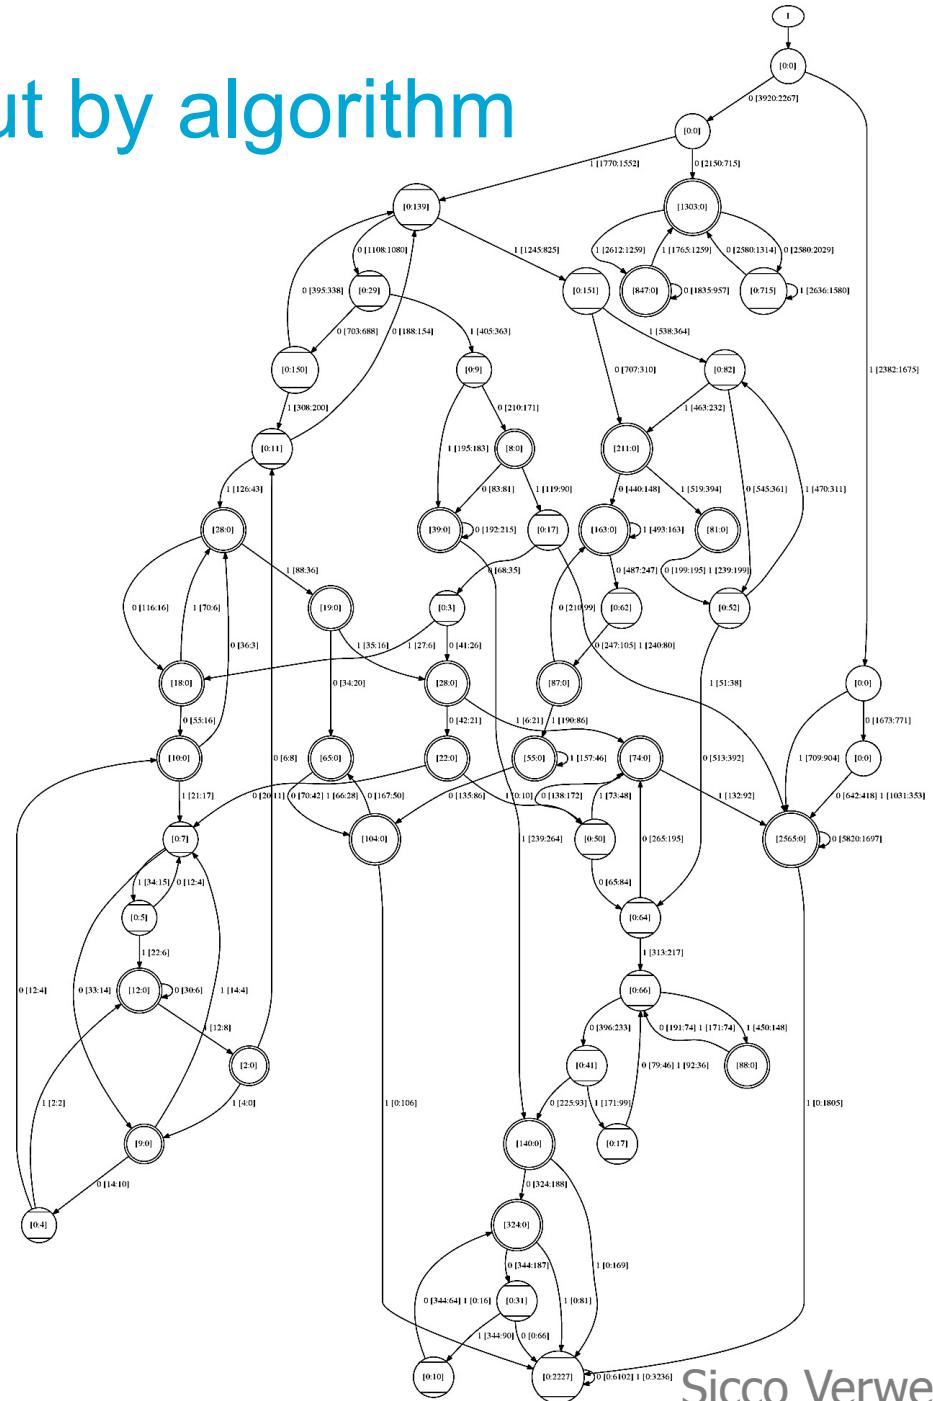

# Example output by algorithm

accept:

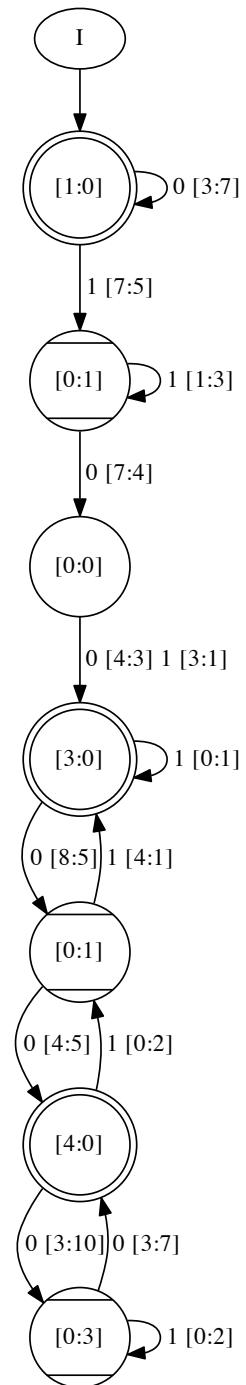

```
1 0 0 0 0 0 0 0  
0 1 1 0 0 0 1 0 1 0 1 0 1 0 1 0 0  
0 0  
1 0 1 0 0  
1 0 0  
1 0 1  
1 0 1  
1 0 0 0 0 0 0
```

reject:

```
0 1 0 0 0  
1 1 0 0 0 0 0 0 1 0 0  
0 0 0 0 0 1  
1 0 0 0 0 1 0 1 0 0 0 0 1 1 1 0 0 0  
0 1 1 1 0 1 0 0 0 0 0 0 0
```

# What does a state mean?

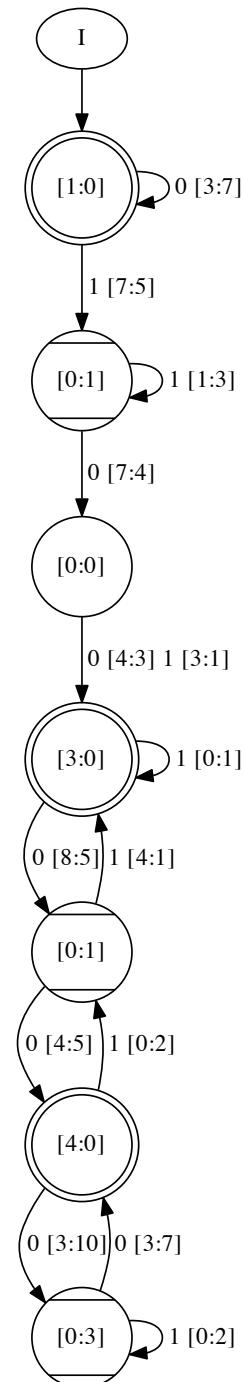

# What does a state mean?

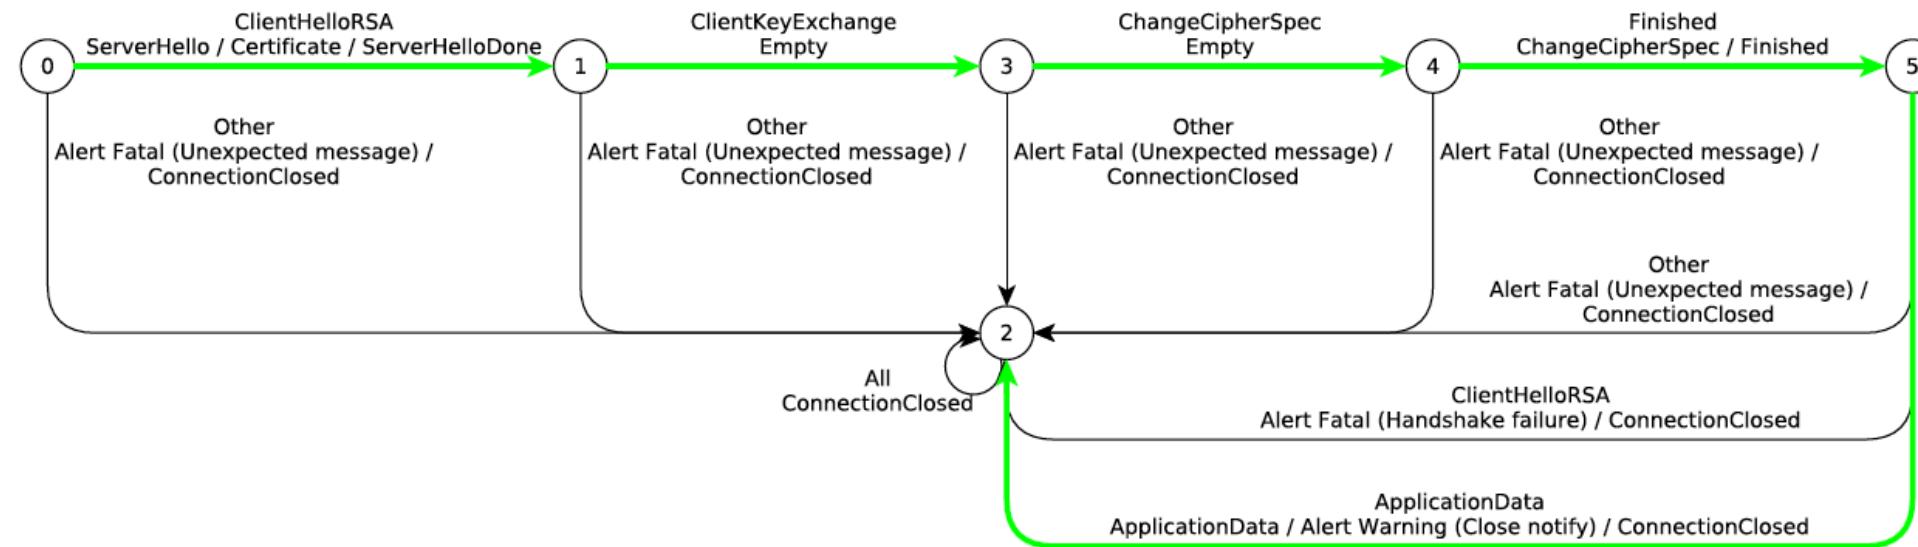

1. A state  $q$  represents **possible futures**  
*all sequences starting in  $q$*
2. A state  $q$  is **independent of the past**  
*no matter how  $q$  is reached, the futures remain the same*

Intuitively, a state means the condition of a system, e.g.:

- initial states
- working states
- error states
- ...

# Key Theory: Myhill-Nerode

- A **necessary** and **sufficient** condition (if and only if) for a language to be **regular**
  - Characterises when finite state machines exist
  - We use it for learning such state machines

# Myhill-Nerode

- Given a language  $L$ , and a pair of strings  $x$  and  $y$ , define a **distinguishing extension** to be a string  $z$  such that exactly one of the two strings  $xz$  and  $yz$  belong to  $L$ .
- Define a **relation  $R$**  on the strings by the rule that
  - $x R y$
  - if there is no distinguishing extension for  $x$  and  $y$ .
- It is easy to show that  $R$  is an **equivalence relation**.
- $L$  is regular if and only if  $R$  has a **finite number of equivalence classes** (sets of  $R$ -equivalent strings).
- Moreover, the number of states of the smallest deterministic finite state automaton recognizing  $L$  is equal to the number of equivalence classes in  $R$ .

# Myhill-Nerode

# Using state machines

- Analyzing the models by hand, or with model checker, for flaws
  - to see if *all paths* are correct & secure
- Fuzzing or model-based testing
  - using the diagram as basis for “deeper” fuzz testing
- Program verification
  - *proving* that there is no functionality beyond that in the diagram, which using testing you can never establish
- Using it when doing a manual code review

(a,+) (b,-) (aba,+) (abaa,-) (bbb,+) (bba,+)

Try to make state machine...

It is **inconsistent!**

(b and bb end in same state,  
but bbb does not)

a	b	ba	aba	aa	baa	abaa	bb	bbb	bba
					0			1	1
					0			1	
ab		1			0				
aba	1	0							
abaa	0								
bb		1	1						
bbb	1								
bba	1								

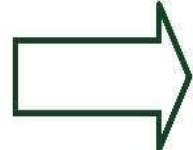

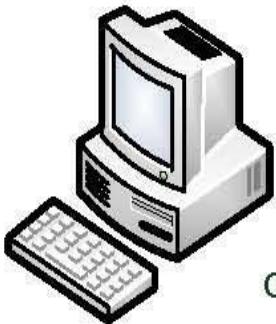

The diagram illustrates the state transitions based on the table above. States are represented by colored circles: blue for '-' (initial state), orange for 'a', green for 'ab', light green for 'aba', yellow for 'aa', orange for 'b', light green for 'bb', yellow for 'bba', and light orange for 'abaa'. Transitions are labeled with symbols from the table. The diagram shows several inconsistencies:

- 'a' leads to 'ab' (orange) and 'aa' (yellow).
- 'ab' leads to 'aba' (light green) and 'aa' (yellow).
- 'aa' leads to 'abaa' (orange) and 'bba' (yellow).
- 'b' leads to 'abaa' (orange) and 'bba' (yellow).
- 'bb' leads to 'abaa' (orange) and 'bba' (yellow).
- 'bbb' leads to 'abaa' (orange) and 'bba' (yellow).
- 'bba' leads to 'abaa' (orange) and 'bba' (yellow).

Specifically, the transitions from 'b' and 'bb' to 'abaa' and 'bba' are shown as crossed-out lines, indicating they are invalid or inconsistent with the table.

Ask: bb

	_	a	b	ba	aba	aa	baa	abaa	bb	bbb	bba
_	1	0		1				0		1	1
a	1			1			0				
b	0		1	1					1		
ab		1				0					
aba	1	0									
abaa	0										
bb	1	1	1								
bbb	1										
bba	1										

If + \_ distinguishes between b and bb

Ask: bb

	-	a	b	ba	aba	aa	baa	abaa	bb	bbb	bba
-	1	0		1				0		1	1
a	1			1			0				
b	0		0	1					1		
ab		1				0					
aba	1	0									
abaa	0										
bb	0	1	1								
bbb	1										
bba	1										

If - b distinguishes between b and bb

# Active learning with L\*

- Aims to discover:
  - **access strings**, smallest strings for every color
  - **one-letter extensions**, and
  - their **distinguishing suffixes**
- Maintains a distinguishing table
- Which distinguishing suffixes is determined during learning

	—	a
—	1	0
a	0	1
b	1	1
aa	1	0
ab	1	0
ba	1	0
bb	0	1

# Active learning with L\*

- Start with an empty table, with one access string and one distinguishing extension:
  - \_ and \_
- Ask membership queries for \_ and its one letter extensions:
  - \_ in L?  $\rightarrow$  yes
  - a in L?  $\rightarrow$  no
  - b in L?  $\rightarrow$  yes

	-
-	1
a	0
b	1

# Active learning with $L^*$

- Can we construct a state machine?
  - No!
  - a points to a new state
- Ask membership queries for its one-letter extensions:
  - aa in  $L$ ?  $\rightarrow$  yes
  - ab in  $L$ ?  $\rightarrow$  yes

—	—
—	1
a	0
b	1
aa	1
ab	1

# Active learning with $L^*$

- Can we construct a state machine?
  - Yes!
- Ask an equivalence query:
  - $L(M) = L? \rightarrow$  no,  $M$  for instance accepts `aabbaa`

—	—
—	1
<b>a</b>	0
<b>b</b>	1
<b>aa</b>	1
<b>ab</b>	1

# Active learning with $L^*$

- $C = aabbaa, -$
- Where does M make a mistake?
  - Replace c prefixes with reached access strings
- Ask membership queries:
  - $_bbaa$  in  $L$ ?  $\rightarrow$  no
  - $_baa$  in  $L$ ?  $\rightarrow$  no
  - $_aa$  in  $L$ ?  $\rightarrow$  yes

	-
-	1
a	0
b	1
aa	1
ab	1

# Active learning with $L^*$

- $C = aabbaa, -$
- Where does  $M$  make a mistake?
  - Replace c prefixes with reached access strings
- Ask membership queries:
  - $\_bbaa$  in  $L$ ?  $\rightarrow$  no
  - $\_baa$  in  $L$ ?  $\rightarrow$  no
  - $\_aa$  in  $L$ ?  $\rightarrow$  yes

	-
-	1
a	0
b	1
aa	1
ab	1

aa is a new  
distinguishing extension!

# Active learning with L\*

- Add the column aa
- Ask membership queries to complete the table

	–	aa
–	1	1
a	0	0
b	1	0
aa	1	1
ab	1	1

# Active learning with L\*

- Add the column aa
- Ask membership queries to complete the table
- b points to a new state
- Add its one-letter extensions, ask membership queries to complete

	—	aa
—	1	1
a	0	0
b	1	0
aa	1	1
ab	1	1
ba	1	1
bb	0	0

# Active learning with L\*

- Add the column aa
- Ask membership queries

The table defines a state machine, ask an equivalence query → yes!

Done

complete

	—	aa
—	1	1
a	0	0
b	1	0
aa	1	1
ab	1	1
ba	1	1
bb	0	0

# Active learning with L\*

1. Initialize the distinguishing table T
2. Complete T until it defines a state machine M
3. While( Eq(M) gives a counterexample c )
  1. Use Mem() and c to find a new distinguishing extension d
  2. Add d to T
  3. Complete T until it defines a state machine M

# $L^*$ - some theory

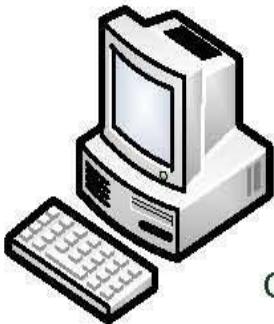

- $L^*$  always finds a state machine for the target language
  - A distinguishing extension can always be found using the counterexample
  - Completing  $T$  terminates since we only have to add one-letter extensions once for every color
  - Once all states are identified,  $\text{Eq}(M)$  will return yes
- $L^*$  runs in polynomial time and from polynomial data!
  - Both  $O(n^2)$ ,  $n$  number of states of smallest target

# Active automaton learning

- Learnlib is an L\* implementation that can be applied to software
  - Uses model-based testing methods for answering equivalence queries
  - We are combining this with fuzzing for security purposes
- The learned models allow to:
  - Investigate the model for any implementation flaws
  - Compare models from different implementations
  - ...
- Demo...

```

# Formalization

- Graph/row coloring works when the Hankel matrix is **infinite** (proof via Myhill-Nerode)
  - otherwise it gives a **lower bound**
- Missing:
  - *row  $i$  and  $j$  have the same color implies:*
    1. *if  $i$  has a 0 in column  $x$ , then  $j$  has a 0 in column  $x$*
    2. *if  $i$  has a 1 in column  $x$ , then  $j$  has a 1 in column  $x$*
    3. ***for all  $a$ , states reached from  $i$  and  $j$  by symbol  $a$  also have the same color!***

# Formalization: exact solutions

1. Encode everything in **Satisfiability**  
DFASAT (Heule and Verwer 2010)
2. Encode the Hankel matrix with suffixes of size up to k  
**kTails** (Biermann and Feldman 1972)
3. Search all colorings using iterative deepening  
**exbar** (Lang 1999)
4. Other (inexact) search strategies
  - Beam search  
(Bugalho and Oliveira 2005)
  - Evolutionary algorithms  
(Lucas and Reynolds 2003)
  - Ant colony optimization  
(Buzhinsky et al. 2014)

# Formalization: approximations

1. State merging, color iteratively, smaller prefix first  
RPNI (Oncina and Garcia 1994)
2. State merging, largest evidence first, **red-blue fringe**  
EDSM (Lang 1998)
3. State merging, ignore negative traces  
DFASAT (Heule and Verwer 1999)
4. State merging, **flexible evidence functions**  
Flexfringe (Verwer and Hammerschmidt 2017)  
also contains DFASAT translation and search wrappers

# Approximation: state merging

- Very effective **greedy** method
  - Initially assume a large DFA
  - Iteratively combine similar states
  - Until no more state can be combined
- Guarantees to find the target state machine in the limit
  - given a polynomial amount of data in the size of the target machine
  - using run-time polynomial in the input data size

obtaining a state machine

# Red-blue fringe state merging

- *To improve speed, use trees!*
  1. Start from a **prefix tree acceptor**
  2. Color the initial state red, and its children blue
  3. For all **consistent** red-blue state pairs R-B
    1. **Merge** B with R
    2. Compute evidence **score**
    3. **Undo merge**
  4. If there is a high scoring and consistent R-B merge
    1. **Merge** B with R
  5. Else
    1. Color B with most occurrences (or most shallow first, ...) red
  6. Color all children of red states blue
  7. Goto 3

    1. Color B with most occurrences (or most shallow first, ..) red
  6. Color all children of red states blue
  7. Goto 3

efficient active learning  
algorithms use trees as well

# or... solve the NP-hard problem by SAT

- Generate the prefix-tree  $T$
- Initialize the set of colors  $L$
- Construct a SAT formula  $F$  using  $T$  and  $L$
- Solve  $F$  using a SAT solver
- If  $F$  is unsatisfiable add a color to  $L$ , goto 3
- Return the DFA found in step 4

# Satisfiability encoding

Variables	Range	Meaning
$x_{v,i}$	$v \in V; i \in C$	$x_{v,i} \equiv 1$ iff state $v$ has color $i$
$y_{a,i,j}$	$a \in \Sigma; i, j \in C$	$y_{a,i,j} \equiv 1$ iff parents of states with color $j$ and incoming label $a$ have color $i$
$z_i$	$i \in C$	$z_i \equiv 1$ iff an accepting state has color $i$
Clauses	Range	Meaning
$(x_{v,1} \vee x_{v,2} \vee \dots \vee x_{v,k})$	$v \in V$	every state has at least one color
$(\neg x_{v,i} \vee z_i) \wedge (\neg x_{w,i} \vee \neg z_i)$	$v \in V_+; w \in V_-; i \in C$	accepting states cannot have the same color as rejecting states
$(y_{l(v),i,j} \vee \neg x_{p(v),i} \vee \neg x_{v,j})$	$v \in V; i, j \in C$	a parent relation is set when a state and its parent are colored
$(\neg y_{a,i,h} \vee \neg y_{a,i,j})$	$a \in \Sigma; h, i, j \in C; h < j$	each parent relation can target at most one color
Redundant Clauses	Range	Meaning
$(\neg x_{v,i} \vee \neg x_{v,j})$	$v \in V; i, j \in C; i < j$	every state has at most one color
$(y_{a,i,1} \vee y_{a,i,2} \vee \dots \vee y_{a,i,k})$	$a \in \Sigma; i \in C$	each parent relation must target at least one color
$(\neg y_{l(v),i,j} \vee \neg x_{p(v),i} \vee x_{v,j})$	$v \in V; i, j \in C$	a parent relation forces a state once the parent is colored
$(\neg x_{v,i} \vee \neg x_{w,i})$	$i \in C; (v, w) \in E$	all determinization conflicts explicitly added as clauses

# Replacing Myhill-Nerode by Markov

- Given an **unlabeled dataset**
  - Put the sample probabilities in a Hankel matrix
  - Determine the minimal coloring of the matrix
- Two rows  $r, r'$  can have the same color if
  - $r = c * r'$ ,  $c$  a constant
  - i.e., *if the suffix probability is independent of the prefix!*
- Use, i.e.:
  - State merging
  - Using likelihood ratio test
  - Singular value decomposition

ALERGIA (Carrasco and Oncina 1994)

RTI (Verwer et al. 2010)

both implemented in Flexfringe (Verwer 2017)

Spectral Learning (Hsu 2009)
